GET vs POST in HTTP

1. Introduction

GET and POST are two common methods used in HTTP. They help the browser and the server communicate with each other. However, each method has a different use.

2. What is GET?

GET is an HTTP method used to request data from a server.

When we use GET, the data is usually sent in the URL. This means the data can appear in the browser's address bar.

Example: When we search for something on Google, GET can be used to send the search request.

Uses of GET:

- Getting information from a server.
  - Searching for information.
  - Opening a web page.

3. What is POST?

POST is an HTTP method used to send data to a server.

The data is usually sent inside the request body, not in the URL.

Example: When we fill out a registration form and click Submit, POST can be used to send our information to the server.

Uses of POST:

- Sending registration information.
  - Submitting a form.
  - Sending data to create a new record.

4. GET and POST: Main Differences

GET: Mainly used to request data from a server.

POST: Mainly used to send data to a server.

GET: Data is usually sent in the URL.

POST: Data is usually sent in the request body.

GET: Requests can be saved in browser history and bookmarks, and may be cached.

POST: Request data is not normally saved in browser history or bookmarks, and POST requests are not cached by default.

GET: Should not be used to change data on the server.

POST: Can be used to create or change data on the server.

5. Important Note

POST does not automatically make data secure. HTTPS is needed to protect data while it travels between the browser and the server.

6. Conclusion

In conclusion, GET and POST are important HTTP methods. GET is mainly used to request information from a server, while POST is mainly used to send data to a server. The choice depends on what we want to do on a website.
